

1. If $\mathbf{A} \in \mathbf{R}^{n \times n}$ is invertible, then for any $\mathbf{b} \in \mathbf{R}^n$, there exists a unique solution to the linear system

$$\mathbf{A}\mathbf{x} = \mathbf{b}.$$

2. For any vector $\mathbf{x} \in \mathbf{R}^n$, it holds that $\|\mathbf{x}\|_1 \leq \|\mathbf{x}\|_\infty$. Recall that, by definition,

$$\|\mathbf{x}\|_1 := |x_1| + \cdots + |x_n|, \quad \|\mathbf{x}\|_\infty = \max\{|x_1|, \dots, |x_n|\}.$$

3. For a vector norm $\|\bullet\|$ on \mathbf{R}^n (for example a p -norm), the *subordinate* matrix norm is defined by

$$\begin{aligned} \|\mathbf{A}\| &:= \max\{\|\mathbf{A}\mathbf{x}\| : \|\mathbf{x}\| \leq 1\} \\ &= \max\left\{\frac{\|\mathbf{A}\mathbf{x}\|}{\|\mathbf{x}\|} : \mathbf{x} \neq \mathbf{0}\right\}. \end{aligned}$$

We recall that the two definitions are equivalent. Then it holds that

$$\forall \mathbf{x} \in \mathbf{R}^n, \quad \|\mathbf{A}\mathbf{x}\| \leq \|\mathbf{A}\| \|\mathbf{x}\|.$$

4. Let $\|\bullet\|$ denote a matrix p -norm, with $p \in [1, \infty)$. Then for all $\mathbf{A} \in \mathbf{R}^{n \times n}$, it holds that $\|\mathbf{A}^2\|_p < \|\mathbf{A}\|_p^2$, with a strict inequality.

5. Consider the matrix

$$\mathbf{A} = \begin{pmatrix} 5 & 1 \\ 1 & 5 \end{pmatrix}.$$

Then it holds that $\|\mathbf{A}\|_2 \leq 10$. Recall that for a symmetric matrix \mathbf{A} , its 2-norm is given by the largest absolute eigenvalue.

6. If all the eigenvalues of a general matrix \mathbf{A} (not necessarily symmetric) are positive, then there exists a unique lower triangular matrix $\mathbf{C} \in \mathbf{R}^{n \times n}$ such that $\mathbf{A} = \mathbf{C}\mathbf{C}^T$.

7. The computational cost of solving the linear system $\mathbf{A}\mathbf{x} = \mathbf{b}$, with a diagonal matrix $\mathbf{A} \in \mathbf{R}^{n \times n}$ and a vector $\mathbf{b} \in \mathbf{R}^n$, scales as $2n^3 + \mathcal{O}(n^2)$.

8. The only matrix $\mathbf{A} \in \mathbf{R}^{n \times n}$ such that $\kappa_2(\mathbf{A}) = 1$ is the identity matrix.

9. Let $\mathbf{A} \in \mathbf{R}^{n \times n}$ be a symmetric matrix. In this case, the matrix can be decomposed as

$$\mathbf{A} = \mathbf{Q}\mathbf{\Lambda}\mathbf{Q}^T,$$

for a diagonal matrix $\mathbf{\Lambda}$ containing the eigenvalues and an orthogonal matrix \mathbf{Q} . Then $\mathbf{A}^k \rightarrow \mathbf{0}$ in the limit $k \rightarrow \infty$ if and only if the spectral radius satisfies $\rho(\mathbf{A}) < 1$.

10. Suppose that $\mathbf{A} \in \mathbf{R}^{n \times n}$ is symmetric and positive definite, and let $\mathbf{b} \in \mathbf{R}^n$. Consider the following iterative method for solving the linear system $\mathbf{A}\mathbf{x} = \mathbf{b}$:

$$\mathbf{x}^{(k+1)} = \mathbf{x}^{(k)} + \omega (\mathbf{b} - \mathbf{A}\mathbf{x}^{(k)}). \quad (1)$$

If $\omega \neq 0$ and this iteration converges to some vector $\mathbf{x}^\infty \in \mathbf{R}$, then \mathbf{x}^∞ is the solution of the linear system.

11. **Bonus:** Suppose that $\mathbf{A} \in \mathbf{R}^{n \times n}$ is symmetric and positive definite. We proved in class that the iteration (1) converges to the exact solution if and only if

$$\rho(\mathbf{I} - \omega\mathbf{A}) := \max_{\lambda \in \sigma(\mathbf{A})} |1 - \omega\lambda| < 1.$$

Assuming that all the eigenvalues of \mathbf{A} are contained in the interval $[1, 2]$, write a sufficient condition on the real parameter ω to guarantee that the iteration converges.

Your answer: It suffices that $\omega \in$

12. **Bonus:** Suppose again that $\mathbf{A} \in \mathbf{R}^{n \times n}$ is symmetric and positive definite. We proved in class that the error for Richardson's iteration (1) satisfies

$$\forall k \in \mathbf{N}, \quad \left| \mathbf{x}^{(k)} - \mathbf{x}_* \right| \leq \rho(\mathbf{I} - \omega\mathbf{A})^k \left| \mathbf{x}^{(0)} - \mathbf{x}_* \right|.$$

Assuming that all the eigenvalues of \mathbf{A} are contained in the interval $[1, 2]$, what value of *omega* would you choose to optimize this bound, that is to say to minimize the factor $\rho(\mathbf{I} - \omega\mathbf{A})$?

Your answer:
